Morbidity and Mortality

Weekly Report

PUBLIC HEALTH SERVICE U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

Prepared by the

COMMUNICABLE DISEASE CENTER

MElrose 4-5131

For release June 2, 1961

Atlanta 22, Georgia

Vol. 10, No. 21

Provisional Information on Selected Notifiable Diseases in the United States and on Deaths in Selected Cities for Week Ended May 27, 1961

Hepotitis - The current weekly total of 1,611 cases represents a slight increase over the 1,535 cases reported last week. The tabulation of hepatitis cases by age appears on page 8. Notable adult concentrations continue particularly in the Eastern Seaboard States of Massachusetts, Connecticut, New York, and New Jersey, but are also evident in Minnesota, Washington, and New Mexico.

Poliomyelitis — Reported this week from seven different States were 9 cases, 6 of which were paralytic. An additional paralytic case was reported by the Commonwealth of Puerto Rico. This week's cases bring the total in 1961 through May 20 to 171 cases, 111 paralytic.

Polio (cumulated weekly) through the 21st Week for the Past 5 Years

EPIDEMIOLOGICAL REPORTS

Anthrax in Man in the United States - 1960

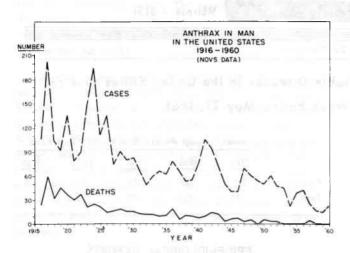

During 1960, 23 cases of human anthrax without any deaths were reported to the Anthrax Investigations Unit of

Anthrax - N. Carolina 1.

the Communicable Disease Center. All represented cutaneous lesions on exposed areas of the body. Twenty (87 percent) of these cases occurred among industrial workers, 16 having contact with proved contaminated goat hair, 3 with proved contaminated wool, and 1 case in a stevedore who handled both hides and wool. Two were agricultural-associated cases: one occurred in a veterinarian who autopsied animals that died of anthrax. The second agricultural-associated case had contact with sheep prior to developing his lesion. The remaining case occurred in a refrigerator repairman who had no known contact with Bacillus anthracis infected materials.

Fifteen of the industrial cases occurred at one mill in South Carolina which, during the past year, began to process imported raw goat hair, work formerly done in its Philadelphia and North Carolina mills, among whose employees cases of cutaneous anthrax had been seen. Two cases were reported from Massachusetts, and single cases were reported from New Hampshire, New Jersey, Pennsylvania, New York, Arkansas and Illinois.

The 23 cases reported in 1960 represents an increase from the 15 cases reported in 1959 and 17 cases reported in 1958. During the past 45 years, however, the annual number of cases reported has been gradually decreasing as shown in the graph above.

Salmonellosis - Washington

On April 10, 1961, a three year old female resident

of Spokane, Washington became ill with symptoms of abdominal cramping, fever and severe bloody diarrhea. Stool culture yielded a group B Salmonella which later proved to be Salmonella typhimurium. Epidemiologic investigation revealed that four of six remaining members of the family of the index case experienced similar illnesses, although less severe, all with onset on April 15. In addition, 3 similar cases were reported in a family of five persons living temporarily in the same household, both with onsets on April 17th. Five other families living in or near Spokane, with whom the index case had contact since April 1 were investigated and in one of these families 2 additional cases were recorded. In every case, illness occurred between one and seven days after contact with the 3 year old index case. On April 19 and 20, stool specimens were obtained from 30 of 38 persons from the seven families investigated. Of the ten persons who had experienced illness, eight yielded S. typhimurium. The same organism was also isolated from one person in each of two contact families in which no clinical illness was reported. Although the source of infection in the three year old index case remains undetermined, it appears possible that this child may have infected twelve persons representing five families and caused clinical salmonellosis in ten of the twelve. Transmission was likely through intimate contact or food contamination, although no single meal was common to all involved persons.

(Submitted by Dr. Ernest A. Ager, Head, Communicable Disease Control, State of Washington Department of Health.)

The chart shows the number of deaths reported for 117 major cities of the United States by week for the current year, a 5-week moving average of these figures plotted at the central week, and an adjusted average for comparison. For each region the adjusted average was computed as follows: From the total deaths reported each week for the years 1956-1960, 3 central figures were selected by eliminating the highest and lowest figure reported for that week. A 5-week moving average of the arithmetic mean of the 3 central figures was then computed with adjustment to allow for population growth in each region. The average value of the regional increases was 2 percent which was incorporated in the adjusted average shown in the chart.

Table 4 shows the number of death certificates re-

ceived during the week indicated for deaths that occurred in selected cities. Figures compiled in this way, by week of receipt, usually approximate closely the number of deaths occurring during the week. However, differences are to be expected because of variations in the interval between death and receipt of the certificate and because of incomplete reporting due to holidays or vacations. If a report is not received from a city in time to be included in the total for the current week, an estimate is used.

The number of deaths in cities of the same size may also differ because of variations in the age, race, and sex composition of the populations and because some cities are hospital centers serving the surrounding areas. Changes from year to year in the number of deaths may be due in part to population increases or decreases.

SOURCE AND NATURE OF MORBIDITY DATA

These provisional data are based on reports to the Public Health Service from the health departments of each State and Puerto Rico. They give the total number of cases of certain communicable diseases reported during the week usually ended the preceding Saturday. Total figures for the United States and the Pacific Division include data for the States of Alaska and Hawaii. Cases of anthrax, botulism, and rabies in man are not shown in table 2, but a footnote to table 1 shows the States reporting these diseases. When diseases of rare occurrence are reported by a State (cholera, dengue, plague, louse-borne relapsing fever, smallpox, louse-borne epidemic typhus, and yellow fever) this is noted below table 1.
